# EXERCISE 1

# Exercise 1

Consider the Weibull distribution:

$$F_T(t) = 1 - e^{-\beta t^\alpha}, \quad f_T(t) = \alpha \beta t^{\alpha-1} e^{-\beta t^\alpha}$$

with  $\alpha = 1.5, \beta = 1$

1. Sample  $N=400$  values from  $f_T(t)$
2. Verify whether the obtained distribution provides a good approximation of the Weibull distribution. To this aim, you are required to:
  - A. find the empirical probability density function (pdf) of the sampled value in 1
  - B. compare the empirical pdf found in 2A. with the analytical Weibull distribution.
3. Provide an estimate  $G_N$  of  $\int_0^{+\infty} t f_T(t) dt$
4. Estimate the variance of  $G_N$

## Useful commands

- `np.random.rand(N)`: provides N random numbers sampled from a uniform distribution in the range  $[0,1)$
- `num_samples = matplotlib.pyplot.hist(Y, bins)` bins the elements of Y into the bins defined by bins and returns the number of elements in each counter.

## Sampling random number from $F_X(x)$

## Example: Weibull Distribution

- Time-dependent hazard rate  $\lambda(t) = \beta\alpha t^{\alpha-1}$

**cdf:**  $F_T(t) = P\{T \leq t\} = 1 - e^{-\beta t^\alpha}$

**pdf:**  $f_T(t) \cdot dt = P\{t \leq T < t + dt\} = \alpha\beta t^{\alpha-1} e^{-\beta t^\alpha} \cdot dt$

- Sampling a failure time  $T$  (by the inverse transform)

$$R \equiv F_R(r) = F_T(t) = 1 - e^{-\beta t^\alpha}$$

$$T = F_T^{-1}(R) = \left( -\frac{1}{\beta} \ln(1 - R) \right)^{\frac{1}{\alpha}}$$

# EXERCISE 2

## Exercise 2

Write the MC code for the estimation of the **time dependent reliability** and **instantaneous availability** of a continuously monitored component with constant failure ( $\lambda$ ) and repair ( $\mu$ ) rates

| values    |                                   |
|-----------|-----------------------------------|
| $\lambda$ | $3 \cdot 10^{-3} \text{ h}^{-1}$  |
| $\mu$     | $25 \cdot 10^{-3} \text{ h}^{-1}$ |

- You can assume a mission time of  $10^3$  time units
- You can compute the time dependent reliability and the instantaneous availability at all times:  $0, 1, 2, 3, \dots, 10^3$

# Exercise 2

## Estimation of the System Reliability

## Estimation of the System Availability

# EXERCISE 3

## Exercise 3

Consider the discrete probability distribution  $f_X(x)$  in the graph:

- 1) Identify the value of the parameter  $A$ ;
- 2) Compute the corresponding cumulative distribution;
- 3) Write a Matlab/Python code to sample  $N=10000$  values from  $f_X(x)$ ;
- 4) Verify that the samples are distributed according to  $f_X(x)$ .

# EXERCISE 4

## Exercise 4

Consider the system in figure composed of three components (A, B, C). Each component can be in two different health states (1-nominal, 2-failed) with exponentially distributed transition times between them. Assuming a mission time  $T = 500 \text{ hours}$ , write the MC code for the estimation of:

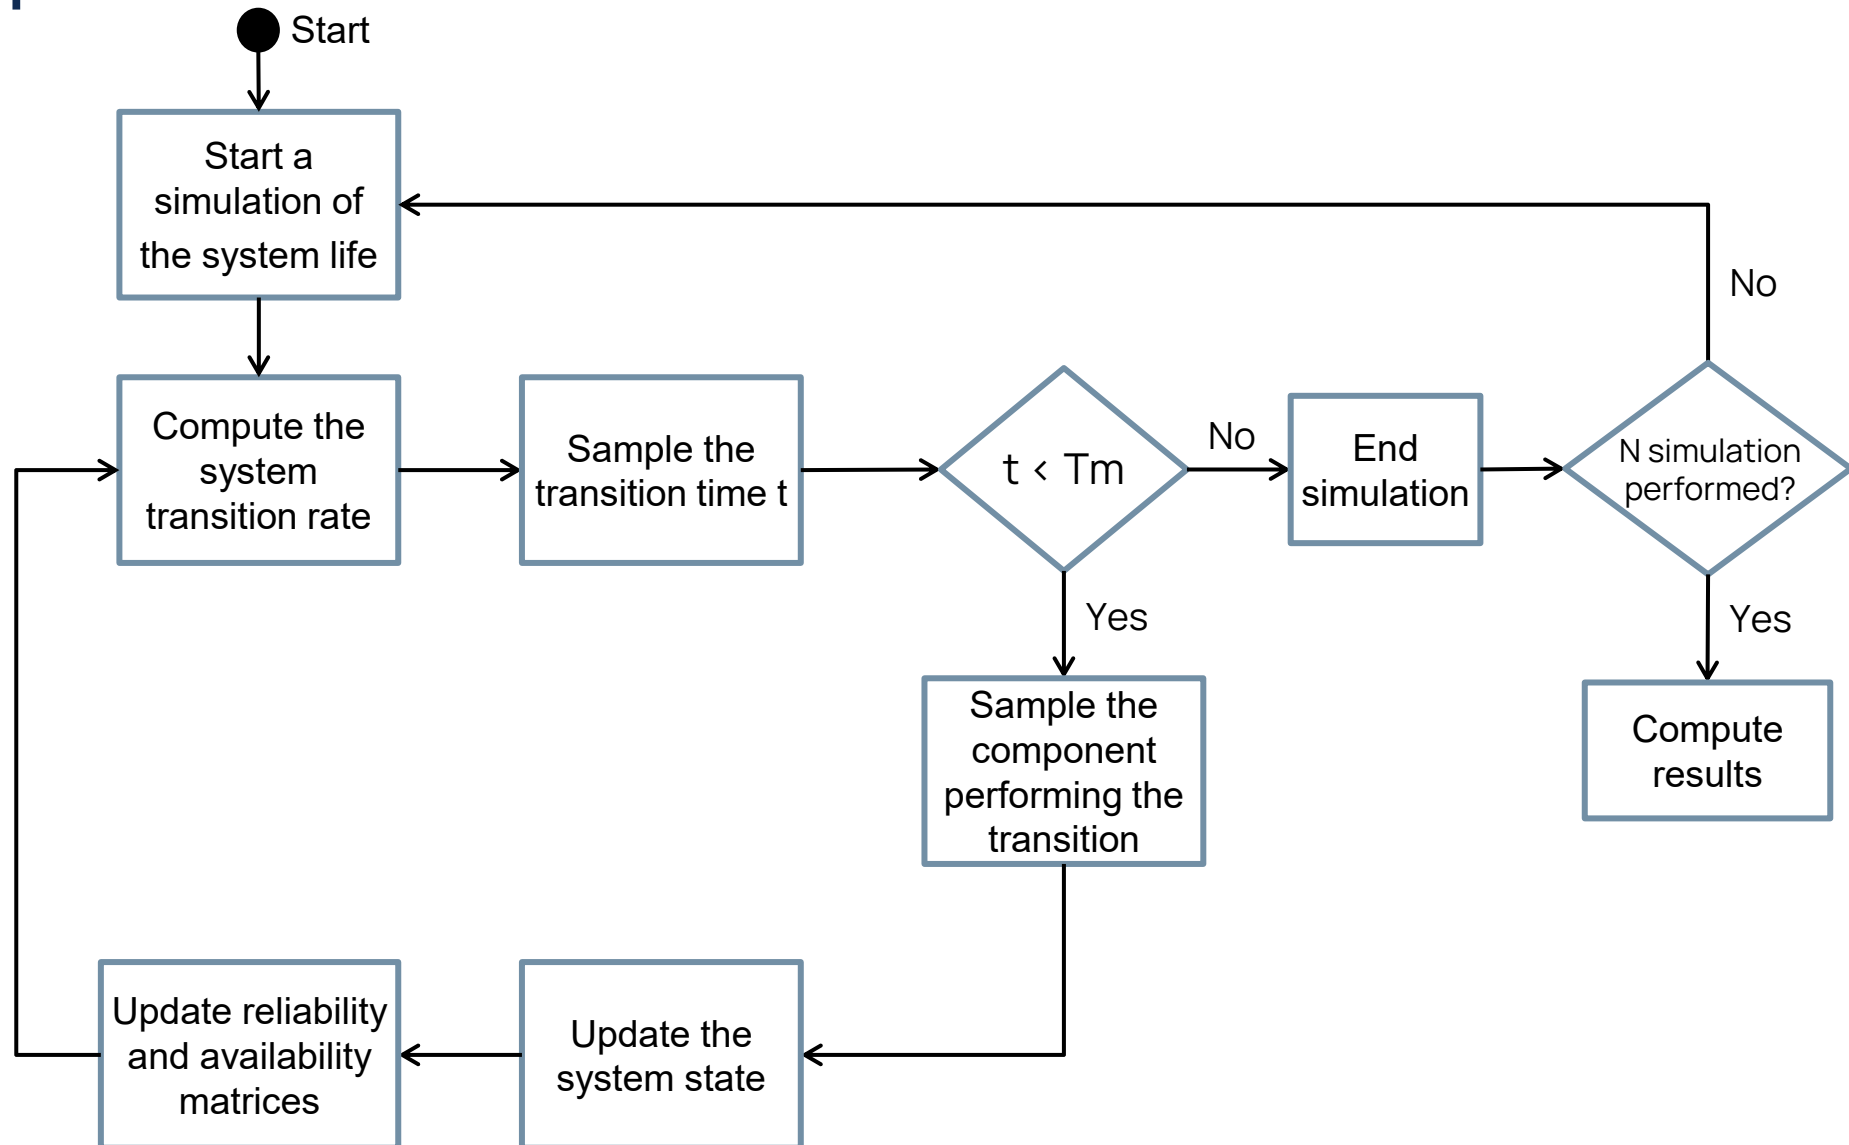

- The time dependent reliability
- The instantaneous availability.
- The estimators uncertainty

|           | 1                                | 2                                | 3                                |
|-----------|----------------------------------|----------------------------------|----------------------------------|
| $\lambda$ | $1 \cdot 10^{-3} \text{ h}^{-1}$ | $2 \cdot 10^{-2} \text{ h}^{-1}$ | $5 \cdot 10^{-2} \text{ h}^{-1}$ |
| $\mu$     | $3 \cdot 10^{-2} \text{ h}^{-1}$ | $5 \cdot 10^{-2} \text{ h}^{-1}$ | $5 \cdot 10^{-3} \text{ h}^{-1}$ |

# Flow diagram

## Sampling the time of transition

- The rate of transition of the system out of its current configuration
- $(1, 1, 1)$  is:

$$\lambda^{(1,1,1)} = \lambda_{1 \rightarrow 2}^A + \lambda_{1 \rightarrow 3}^A + \lambda_{1 \rightarrow 2}^B + \lambda_{1 \rightarrow 3}^B + \lambda_{1 \rightarrow 2}^C + \lambda_{1 \rightarrow 3}^C$$

- We are now in the position of sampling the first system transition time  $t_1$ , by applying the **inverse transform method**:

$$t_1 = t_0 - \frac{1}{\lambda^{(1,1,1)}} \ln(1 - R_t)$$

where  $R_t \sim U[0,1)$

## Sampling the component performing the Transition

- Assuming that  $t_1 < T_M$  (otherwise we would proceed to the successive trial), we now need to determine which component has undergone the transition
- The probabilities of components A, B, C undergoing a transition out of their initial nominal states 1, given that a transition occurs at time  $t_1$ , are:

$$\frac{\lambda^A}{\lambda^{(1,1,1)}}, \quad \frac{\lambda^B}{\lambda^{(1,1,1)}}, \quad \frac{\lambda^C}{\lambda^{(1,1,1)}}$$

$$\lambda^A = \lambda_{1 \rightarrow 2}^A + \lambda_{1 \rightarrow 3}^A \quad \lambda^B = \lambda_{1 \rightarrow 2}^B + \lambda_{1 \rightarrow 3}^B \quad \lambda^C = \lambda_{1 \rightarrow 2}^C + \lambda_{1 \rightarrow 3}^C$$

- Thus, we can apply the inverse transform method to the discrete distribution

# EXERCISE 5

# Exercise 5

- Components can be in three states and the time of transition from one state to another is exponentially distributed:

| Arrival      | 1                                    | 2                                    | 3                                    |
|--------------|--------------------------------------|--------------------------------------|--------------------------------------|
| Initial      |                                      |                                      |                                      |
| 1 (nominal)  | 0                                    | $\lambda_{1 \rightarrow 2}^{A(B,C)}$ | $\lambda_{1 \rightarrow 3}^{A(B,C)}$ |
| 2 (degraded) | 0                                    | 0                                    | $\lambda_{2 \rightarrow 3}^{A(B,C)}$ |
| 3 (failed)   | $\lambda_{3 \rightarrow 1}^{A(B,C)}$ | $\lambda_{3 \rightarrow 2}^{A(B,C)}$ | 0                                    |

# Exercise 5

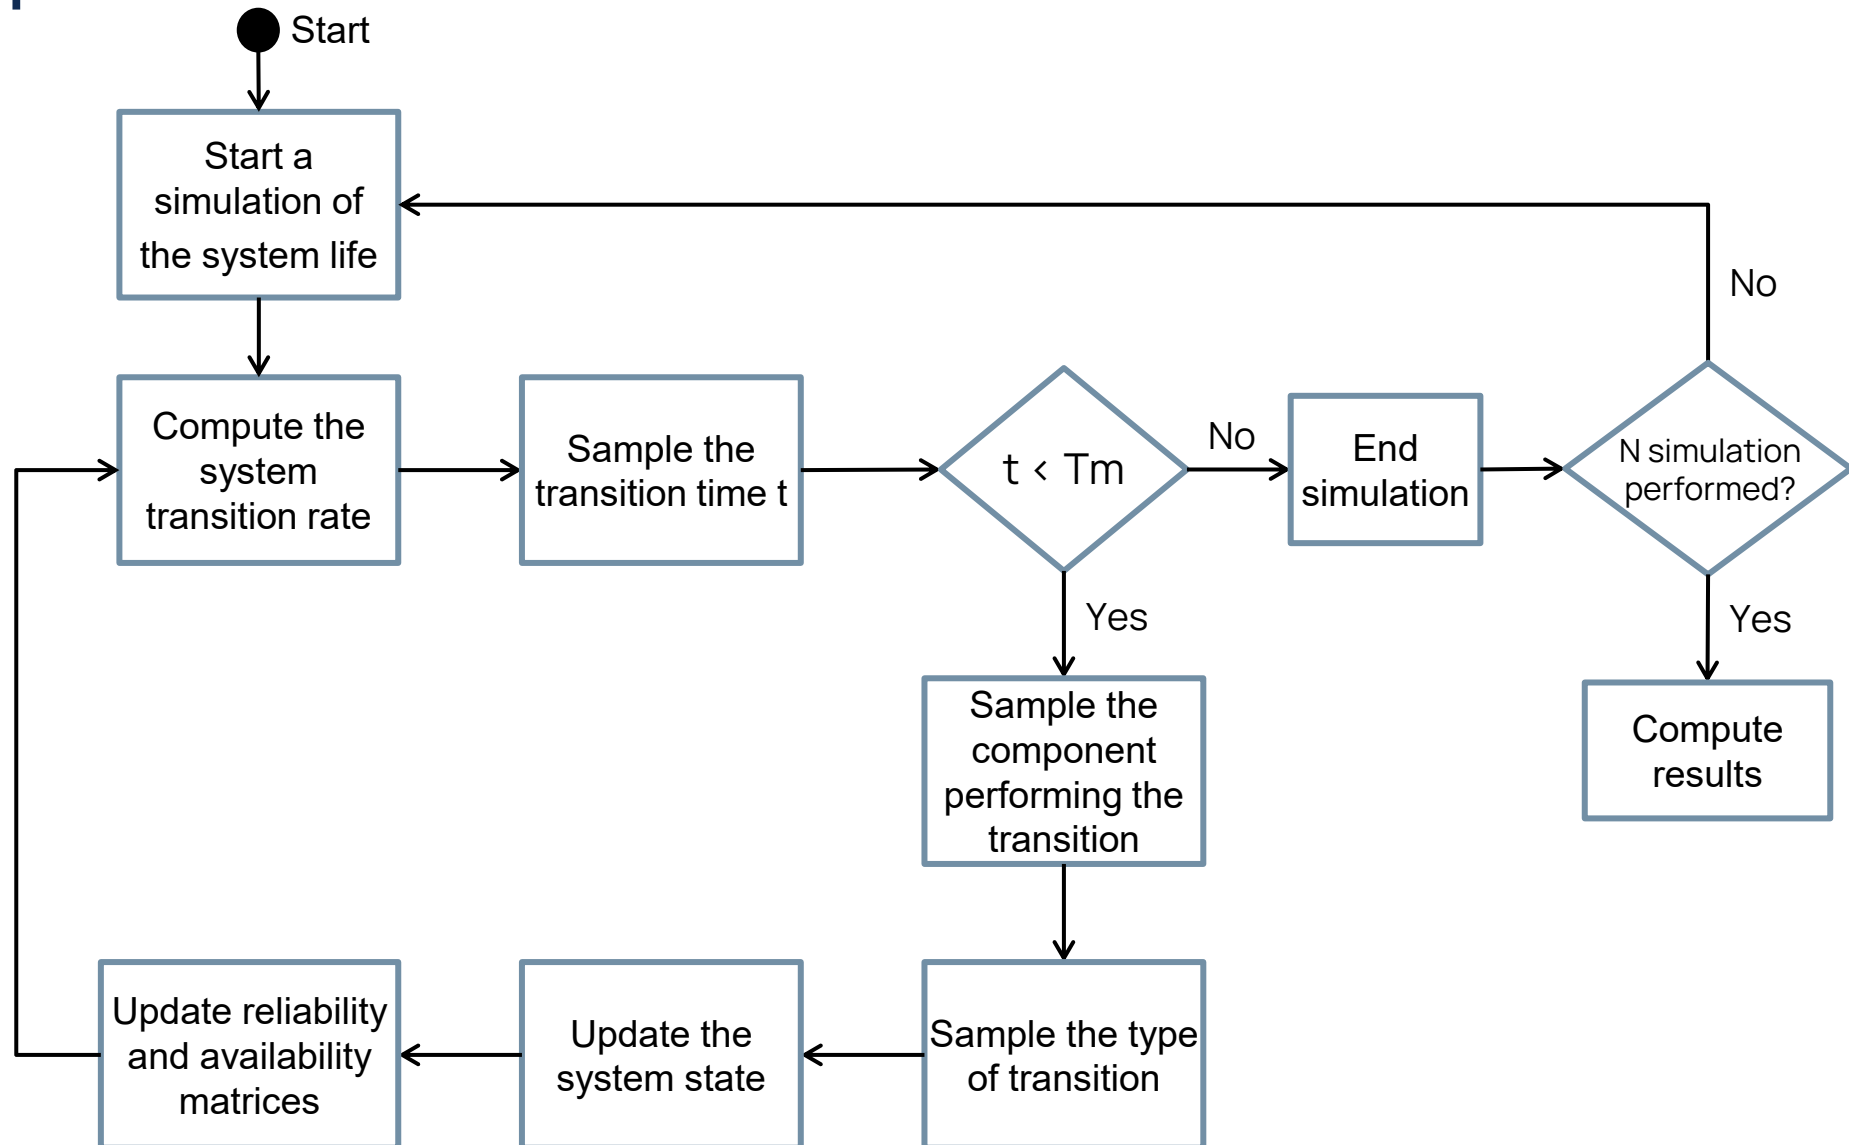

| A | 1                 | 2                 | 3                 |
|---|-------------------|-------------------|-------------------|
| 1 | -                 | $3 \cdot 10^{-3}$ | $10^{-3}$         |
| 2 | -                 | -                 | $6 \cdot 10^{-3}$ |
| 3 | $8 \cdot 10^{-3}$ | $5 \cdot 10^{-3}$ | -                 |

| B | 1                   | 2                   | 3                 |
|---|---------------------|---------------------|-------------------|
| 1 | -                   | $1 \cdot 10^{-3}$   | $5 \cdot 10^{-3}$ |
| 2 | -                   | -                   | $4 \cdot 10^{-3}$ |
| 3 | $7.5 \cdot 10^{-3}$ | $3.5 \cdot 10^{-3}$ | -                 |

| C | 1                 | 2                   | 3                   |
|---|-------------------|---------------------|---------------------|
| 1 | -                 | $8 \cdot 10^{-3}$   | $2.5 \cdot 10^{-3}$ |
| 2 | -                 | -                   | $2 \cdot 10^{-3}$   |
| 3 | $4 \cdot 10^{-3}$ | $1.5 \cdot 10^{-3}$ | -                   |

- Estimate the **reliability** of the system at  $T_{miss} = 4000$
- Estimate the **time dependent reliability**  $R(t)$
- Estimate the **instataneous availability**  $A(t)$

# Flow diagram

## Sampling the time of transition

- The rate of transition of the system out of its current configuration
- $(1, 1, 1)$  is:

$$\lambda^{(1,1,1)} = \lambda_{1 \rightarrow 2}^A + \lambda_{1 \rightarrow 3}^A + \lambda_{1 \rightarrow 2}^B + \lambda_{1 \rightarrow 3}^B + \lambda_{1 \rightarrow 2}^C + \lambda_{1 \rightarrow 3}^C$$

- We are now in the position of sampling the first system transition time  $t_1$ , by applying the **inverse transform method**:

$$t_1 = t_0 - \frac{1}{\lambda^{(1,1,1)}} \ln(1 - R_t)$$

where  $R_t \sim U[0,1)$

## Sampling the component performing the Transition

- Assuming that  $t_1 < T_M$  (otherwise we would proceed to the successive trial), we now need to determine which component has undergone the transition
- The probabilities of components A, B, C undergoing a transition out of their initial nominal states 1, given that a transition occurs at time  $t_1$ , are:

$$\frac{\lambda^A}{\lambda^{(1,1,1)}}, \quad \frac{\lambda^B}{\lambda^{(1,1,1)}}, \quad \frac{\lambda^C}{\lambda^{(1,1,1)}}$$

$$\lambda^A = \lambda_{1 \rightarrow 2}^A + \lambda_{1 \rightarrow 3}^A \quad \lambda^B = \lambda_{1 \rightarrow 2}^B + \lambda_{1 \rightarrow 3}^B \quad \lambda^C = \lambda_{1 \rightarrow 2}^C + \lambda_{1 \rightarrow 3}^C$$

- Thus, we can apply the inverse transform method to the discrete distribution

## Sampling the kind of Transition

- Since component B is the one undergoing the transition we need to sample the new state of component B.
- The probabilities of components B undergoing a transition out of their initial nominal states 1 given that a transition occurs at time  $t_1$ , are:

$$\frac{\lambda_{1 \rightarrow 2}^B}{\lambda^B} \qquad \frac{\lambda_{1 \rightarrow 3}^B}{\lambda^B}$$

- Thus, we can apply the inverse transform method to the discrete distribution

**Thank you for  
your kind attention**
